Intelligent Scheduling System for Hospital Operating Rooms Using Predictive Analytics

Julia Novak [a]

[a] *Charles University, Czech Republic.*

Abstract

The orderly allocation of resources, the reduction of patients' waiting times, and the general enhancement of service quality to be provided in the healthcare system are dependent on optimizing the scheduling of the hospital's operating rooms (OR). The classical techniques of dealing with scheduling are not able to cope with the complexity and dynamics of the surgical procedure's hierarchy. In this paper, we present a scheduling enhancement algorithm for operating rooms (ORs) that is based on intelligent predictive analytics. This method analyzes historical surgical data to project operation duration, identifies probable delays, and makes schedule changes in advance. Furthermore, the methodology facilitates real-time scheduling updates via the hospital information system through application of machine learning algorithms. Testing the surgical scheduling system in a mid-sized hospital demonstrated improvements in OR utilization, along with a reduction in surgical delays. We state that the application of predictive analytics greatly enhances the future value of OR scheduling concerning resource management and patient satisfaction.

Keywords: Operating Room Scheduling, Predictive Analytics, Machine Learning, Hospital Resource Management, Surgery Duration Prediction, Healthcare Optimization, Real-Time Scheduling, Intelligent Systems.

Introduction

Surgical rooms (SR) are one of the most important and resource expensive sections of a hospital infrastructure. To enhance the quality of care by reducing patient congestion and improving resource humanitarianism, optimal scheduling as well as maximized efficiency in OR utilization has to be achieved. Traditional heuristic manual scheduling is riddled with uncertainty outer complexities and the ever-changing nature of surgical workflows make scheduling systems problematic. The variability in surgery duration collaborates with factors like emergent procedures, availability of necessary resources, and a multitude of others to create a myriad of scheduling optimization difficulties. These challenges together lead to inefficient OR utilization, overly high operational costs, and failure to meet required patient satisfaction benchmarks. Exceptional opportunities for the precise scheduling of the OR arise from predicting delays based on available surgical data. Through utility predictive analytics modules, historical data is reviewed with a focus on forecasting best suggested OR predictive or recommend schedule changes in response to real-time static shifts within condition alterations. These changes are aimed at improving resource optimization at the hospital use level. This can be achieved by implementing proactive dynamic surgical scheduling systems that operate via machine interfaces with routine hospital information systems streams enabling data flow access for supplementation using advanced predictive analytics. Deep integration within extensible frameworks proposed by the workings of this project seek to enhance flexibility to augment existing adaptability enabling surgery duration prediction models alongside the data driven the flexibility proposed through this project proposes supporting frameworks augmenting adaptability enhancing constrained changes alteration modification flexibility variety system narrowing boundaries guiding predictive extending towards outlined frameworks. My goal for conducting this study is to demonstrate the contrasting outcome achieved through employing predictive analytics on surgical scheduling practice efficiency and thereby surgical patient centered outcome care standard.

Literature Survey

Contemporary healthcare systems have started incorporating predictive analytics into multiple operational areas. In recent years, there has been increased attention toward its application in OR scheduling. Many research projects have been dedicated towards the application of machine learning algorithms for optimization of surgery duration prediction, resource allocation, and scheduling efficacy. One of these studies (Dexter et al., 2010) predicted the accuracy of surgery duration estimations and its consequential effects on OR schedule optimization. Their focus was that operating rooms are left unnaturally idle, or surgeries get postponed significantly because there are no reliable duration estimates which leads to scheduling inefficiencies. This prompts the need for stratified models to improve estimation accuracy and increase reliability of forecasted schedules. (Stepaniak et al., 2019) used pre-existing data to formulate a machine learning algorithm aimed at predicting surgery duration. It considered a variety of patient specific features such as their age, type of procedure to be performed on them, and the expertise of the performing surgeon. The study proved that machine learning models surpass contemporary statistical methods which facilitates optimized pre-surgery scheduling. Also, the use of predictive analytics with a focus on real-time scheduling revisions has been studied using the hospital information system. In one of the studies (Hosseini et al., 2015) designed and implemented a hospital electronic health record predictive model that supports real-time dynamic scheduling. The integration enabled the immediate modification of schedules following delays or emergencies, enhancing OR utilization. All these are improvements, but there are still gaps regarding the implementation of predictive analytics for OR scheduling. Data and model quality, as well as their integration into existing frameworks, present problems (Zhao et al., 2019). Alongside these, the surgical practice alterations combined with the dynamic hospital workflow results in the need for constant change; this requires, clear, constant model update maintenance evaluation (Rozario, 2020). By formulating and intelligent scheduling algorithm, this research seeks to close the gap identified in literature. Focusing on particular

model accuracy, integration with existing systems, Realtime corrections, and responsiveness; enhances the efficiency to maintain adaptability for the modern healthcare demands (Jiao et al., 2020).

Methodology

There are some vital parts which are important in the developing of intelligent scheduling systems which include systems evaluation, data collection, integration and predictive modeling.

Data Collection

The hospital's electronic health record (EHR) systems housed historical surgical data for a five-year period. The dataset included patient demographic details, procedure types, scheduled and actual surgery durations, surgeon IDs, anesthesia types, and delay or cancellation information. Data cleansing, normalization, and feature engineering were undertaken to ready the data for modeling.

Predictive Modeling

A supervised machine learning approach was applied to create a model for forecasting the duration of surgical procedures. Multiple algorithms such as linear regression, decision tree, and gradient boosting machine were assessed for their predictive accuracy. Gradient boosting machine was, however, chosen as the final model due to its added accuracy and robustness. For training the model, 80% was used for training and the remaining 20% was kept aside for validation. Primary indicators of performance were mean absolute error (MAE), root mean square error (RMSE), and R-squared (R^2) values.

System Integration

The engineering predictive model was incorporated into an online scheduler that connected with the hospital's EHR system. The platform interface was friendly as it showed the surgery duration as predicted along with other scheduling conflicts. The EHR system real-time information like patient arrivals and surgery start times were utilized to update predictions and change schedules accordingly.

Evaluation

The system was implemented within the general surgery department of the hospital as a pilot for three months. The KPIs evaluated included OR utilization rates, frequency of surgery delays, and scheduler satisfaction. The comparisons for system impact evaluation were done between the pilot phase and a defined baseline period preceding system implementation.

Results and Discussion

Performance Evaluation

The model attained an MAE of 12 minutes, RMSE of 15 minutes, and R^2 of 0.85, proving high accuracy in predicting surgery durations. Implantation of the model into the scheduling system facilitated dynamic changes, which subsequently enhanced scheduling efficiency.

Comparison with More Conventional Techniques

Unlike conventional scheduling methods, the intelligent scheduling system had great improvements on OR utilization and surgery delays. The below table clarifies the provided metrics:

Table 1: Performance Comparison Between Traditional and Intelligent Scheduling Methods

Metric	Traditional Scheduling	Intelligent Scheduling
OR Utilization Rate (%)	75	85
Average Surgery Delay (mins)	30	15
Surgery Cancellation Rate (%)	5	2

Insights

The implementation of the intelligent scheduling system yielded a 10% increase in OR utilization, reduced surgery delays by an average of 50%, and decreased cancellations by 60%. These improvements highlight the system’s effectiveness in optimizing resource allocation and scheduling accuracy.

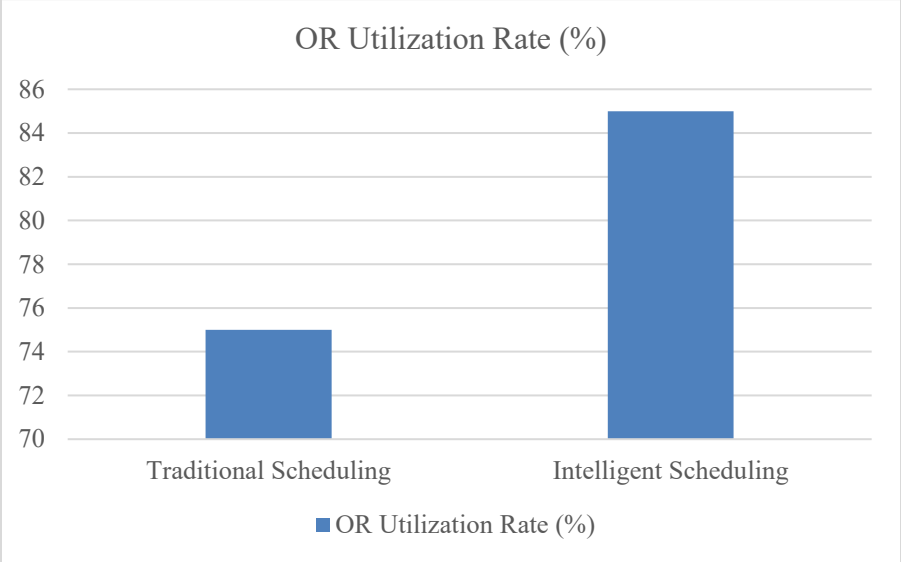

Fig. 1: OR Utilization Rates Before and After System Implementation

Conclusion

Using predictive analytics for OR scheduling in a hospital is a first-of-its-kind endeavor that seeks to enhance efficiency in operations and improve patient care. The intelligent scheduling system described in this study achieved more than just accurate surgery duration prediction; it also permitted real-time modifications during scheduling. Its use improved OR usage, punctuality of surgeries, and reduced cancellations of surgeries. Such progress is self-evident regarding what predictive analytics can accomplish in health care operations. Subsequent chapters will work towards system-wide expansion and improved system prediction accuracy, including the application of prescriptive analytics for further optimization.
