

Influence of Sibinin on DMBA Induced Hepatotoxicity and Free-Radical Damage in Norwegian Rat, *Rattus norvegicus*

Vitthalrao B. Khyade

“Dr. APIS”, Shrikrupa Residence, Teachers Society, Malegaon Colony (Baramati) Dist. Pune – 413115. India.

Abstract

7,12-Dimethylbenz[a]anthracene (DMBA) is acting as immunosuppressor and it serves as a tumor initiator. Tumor promotion can be induced with treatments of 12-*O*-tetradecanoylphorbol-13-acetate (TPA) in some models of two-stage carcinogenesis. This allows for a greatly accelerated rate of tumor growth, making many cancer studies possible. The DMBA damages many internal organs including liver, by inducing the production of reactive oxygen species, DNA-adduct formation and affecting the activities of phase I, II, antioxidant and serum enzymes. The silibinin is a pharmacologically active constituent of *Silybum marianum* (L), with documented antioxidant activity. The aim of present attempt was to evaluate both histopathologically and biochemically whether silibinin is protective in DMBA induced liver damage. Thirty two Norwegian Rats (*Rattus norvegicus* L) were divided into four groups, as follows: 1) control group - oral corn oil was given; 2) DMBA group – DMBA was administered orally 335 mg/kg in the corn oil solution; 3) Silibinin group - 100 mg/kg/day silibinin was given alone orally, every 24 hours for 7 days; 4) Silibinin + DMBA group - DMBA plus silibinin was given. All rats were sacrificed at the end of experiment. Superoxide dismutases (SOD), glutathione peroxidase (GPX), nitric oxide (NO) and myeloperoxidase (MPO) were investigated in serum and liver tissue. In addition, serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) enzyme activities were evaluated. The liver tissue was evaluated histopathologically with Hematoxylin & Eosin dye. Biochemically, ALT, AST, NO, MPO in serum and NO, MPO in liver tissue were found to be significantly higher in DMBA group, compared to control group ($P < 0.001$). In Group Silibinin + DMBA, serum AST, ALT, NO, MPO levels were significantly lower ($P < 0.01$), and both serum and tissue SOD activities were significantly higher, compared to DMBA group ($P < 0.001$). DMBA induced histopathological changes in liver tissue were: severe sinusoidal dilatation, moderate disruption of the radial alignment of hepatocytes around the central vein, severe vacuolization in the hepatocyte cytoplasm, inflammation around central vein and portal region. In rats receiving both DMBA and silibinin, the DMBA induced changes accounted for less sinusoidal dilatation, vacuolization in the hepatocyte

cytoplasm and the inflammation around central vein and portal region ($P < 0.05$). The DMBA was found to induce liver damage by oxidative stress mechanisms. Silibinin reduced the oxidative stress by inducing antioxidant mechanisms, thereby showing protective effect against DMBA induced liver damage. Further studies with silibinin should be performed regarding DMBA toxicity.

Keywords: DMBA; Oxidative Stress; Antioxidants; Histopathology; Liver

INTRODUCTION

7,12-Dimethylbenz[a]anthracene (DMBA) is an immunosuppressor and a powerful organ-specific laboratory carcinogen (Miyata, *et al* , 2001). It is widely used in many research laboratories studying cancer. It serves as a tumor initiator. Tumor promotion can be induced with treatments of 12-*O*-tetradecanoylphorbol-13-acetate (TPA) in some models of two-stage carcinogenesis (Sung, *et al* , 2005). This allows for a greatly accelerated rate of tumor growth, making many cancer studies possible.

Silibinin is the major active constituent of silymarin, a standardized extract of the milk thistle seeds, containing a mixture of flavonolignans consisting of silbinin, isosilbinin, silicristin, silidianin, and others. Silibinin itself is mixture of two diastereomers, silybin A and silybin B, in approximately equimolar ratio (Davis-Searles, *et al* ,2005). The mixture exhibits a number of pharmacological effects, particularly in the liver, and there is some clinical evidence for the use of silibinin as a supportive element in alcoholic and child grade 'A' liver cirrhosis (Saller, *et al* ,2008).

Poor water solubility and bioavailability of silymarin led to the development of enhanced formulations. Silipide (trade name Siliphos), a complex of silymarin and phosphatidylcholine (lecithin), is about 10 times more bioavailable than silymarin (Kidd and Head, 2005). An earlier study had concluded Siliphos to have 4.6 fold higher bioavailability (Barzaghi, 1990). It has been also reported that silymarin inclusion complex with β -cyclodextrin is much more soluble than silymarin itself (Voinovich, 2009). There have also been prepared glycosides of silybin, which show better water solubility and even stronger hepatoprotective effect(Kosina, *et al* , 2002).

Silymarin, as other flavonoids, has been shown to inhibit P-glycoprotein-mediated cellular efflux (Zhou and Chowbay, 2004). The modulation of P-glycoprotein activity may result in altered absorption and bioavailability of drugs that are P-glycoprotein substrates. It has been reported that silymarin inhibits cytochrome P450 enzymes and an interaction with drugs primarily cleared by P450s cannot be excluded (Wu, *et al* 2009).

A phase I clinical trial in humans with prostate cancer designed to study the effects of high dose silibinin found 13 grams daily to be well tolerated in patients with advanced prostate cancer with asymptomatic liver toxicity (hyperbilirubinemia and elevation of alanine aminotransferase) being the most commonly seen adverse event (Thomas, 2007). Silymarin is also devoid of embryotoxic potential in animal models (Fraschini, *et al* , 2002 and Hahn, *et al* , 1968). Silibinin is under investigation to see whether it may have a role in cancer treatment (e.g. due to its inhibition of STAT3 signalling)(Bosch-Barrera and Menendez , 2015). Silibinin also has a number of potential mechanisms that could benefit the skin. These include chemoprotective effects from environmental toxins, anti-inflammatory effects, protection from UV induced photocarcinogenesis, protection from sunburn, protection from UVB-induced epidermal

hyperplasia, and DNA repair for UV induced DNA damage (double strand breaks) (Singh, *et al* , 2009).

Silibinin is a pharmacologically active constituent of *Silybum marianum* (Trappoliere, *et al* , 2009). Its antioxidant activity may have a crucial role in the effects of silibinin. It is widely used in the treatment due to its safety and lack of adverse effects (Trouillas, *et al* , 2008). Recent studies have shown that silibinin protects the liver against multiple drugs and chemical induced liver injury (Gazak, *et al* , 2007 ; Prabu, *et al* , 2012). Silibinin seems to be a promising protective agent for repairing free-radical induced damage in a variety of pathological conditions (Prabu, *et al* , 2012). Aspartate aminotransferases (AST) and alanine aminotransferases (ALT) are intracellular aminotransferase enzymes, present in liver cells. After cell death or damage in liver cells, they are released into the circulation. Increased serum transaminases translate a susceptibility to liver damage (Andreoli, *et al* , 1995). Myeloperoxidase (MPO) is the most abundant protein in neutrophils, catalyzes the conversion of hydrogen peroxide and chloride ions into hypochlorous acid. It plays a role in down regulating the inflammatory response (Klebanoff, 1999). Superoxide dismutase (SOD) is regarded as the first line of defense against the detrimental effects of molecular oxygen radicals in cells. Superoxide is a crucial source of hydroperoxides and free radicals. The activity of SOD inhibits lipid peroxidation by catalyzing the conversion of superoxides into hydrogen peroxide and oxygen. The SOD protects the cells from superoxide toxicity via removing superoxide free radicals (Beyer, *et al* , 1991). Endogenous nitric oxide (NO) is formed from the amino acid L-arginine with nitric oxide synthase (NOS) enzyme. Increasing the level of NO has a crucial role in the modulation of oxidative stress and tissue damage (Tutanc, *et al* , 2012). It was reported that oxidative stress results in the increase of the activity of NO synthase, as a consequence to the elevation of NO release (Peresleni, *et al* , 1996). Glutathione peroxidase (GPx) is a crucial selenocysteine-containing enzyme, which catalyzes the reduction of hydroperoxides, including hydrogen peroxide, by reduced glutathione and functions to protect the cells from oxidative damage (Arthur, 2000). The attempt aimed to evaluate the antioxidant and protective efficacies of silibinin against DMBA induced hepatotoxicity in rats by evaluation of NO, MPO, SOD, GPx, AST, ALT and histological values.

MATERIAL AND METHODS

Thirty two adult female 12 week-old Brown rats (*Rattus norvegicus* L) (Dr. APIS Laboratory), weighing 170 - 220 g were used for the present experiment. The animals were housed in quiet rooms (20 - 25°C; 50 - 60% relative humidity) on a 12 hour light/dark cycle (7 a.m. - 7 p.m.) and allowed a commercial standard rat diet (Abalioglu Yem Sanayi, Denizli, Turkey) and water ad libitum. All animal procedures were approved by the Animal Care and Use Protocol (ACUP). DMBA and Silibinin were purchased from Sigma/Aldrich Chemicals, USA , through local dealer.

The animals were randomly divided into four groups: -

-Group 1: Control group (n = 8); rats were given 0.3 mL corn oil orally;

- Group 2: DMBA group (n = 8); rats were administered a single dose of 335 mg/kg of body weight (BW) of DMBA (Basudin 60 EC, Syngeta Tarım San. ve Tic. AS, Izmir, Turkey) with corn oil (Shah and Iqbal,2010; Yilmaz, *et al* , 2012 and Teimouri, 2007);

- Group 3: Silibinin group (n = 8); silibinin was given orally, 100 mg/kg/day every 24 hours, for 7 days (Arthur, 2000 and Nakagawa and Moore,1999);

- Group 4: DMBA + Silibinin group (n = 8); rats were given DMBA single dose of 335 mg/kg BW of DMBA orally and 100 mg/kg/ day silibinin was administered orally, every 24 hours for 7 days.

At the end of the experiment, all animals were anesthetized under intraperitoneal injection of ketamine/xylazine (60 mg/kg and 6 mg/kg, respectively). Blood samples were taken from intracardiac on the sterile tubes, for measuring the level of serum ALT, AST, MPO, NO, SOD and GPx. Blood samples were centrifuged and serum was separated. The blood was centrifuged at $2000 \times G$ for 15 minutes, at $4^{\circ}C$. The top yellow serum layer was pipetted off, without disturbing the white buffy layer. Livers were removed immediately and washed with phosphate buffer solution (PBS) (pH = 7.4) and then frozen promptly in a deep freezer for biochemical analysis. All samples were protected under $-80^{\circ}C$ until analysis.

(I). Determination of Aspartate Aminotransferase and Alanine Aminotransferase Activities The activities of AST and ALT were calculated spectrophotometrically in serum, using Beckman Coulter kits by autoanalyzer (Unicel D \times C 800 Synchron, Brea, California, USA). The results were expressed as units per liter (U/L).

(II). Determination of Superoxide Dismutase Activity The tissue was homogenized at 16000 rpm on ice, in 5 - 10 mL cold buffer, 20 mM HEPES buffer, pH 7.2, containing 1mM EGTA, 210 mM mannitol and 70 mM sucrose per g tissue. The mixture was centrifuged at $1500 \times G$ for 5 minutes, at $4^{\circ}C$. The supernatant was removed. Serum should be diluted 1:5 with sample buffer. The SOD activity was measured in the supernatant and serum. The SOD was determined via Cayman's Superoxide Dismutase assay kit (Cayman Chemical Co., Ann Arbor, MI, USA) in Bio-Tek ELx-800 (Winooski, USA). The detection of superoxide radicals were generated by xanthine oxidase and hypoxanthine. One unit of SOD is defined as the amount of enzyme required to exhibit 50% dismutation of the superoxide radical. The results were expressed as units per mg protein (U/mg) tissue, for liver tissue, and units per milliliter (U/mL) for serum. The dynamic range of the kits is 0.005 - 0.05 U/mL SOD. Recommended by the company for measuring formulation, the SOD was calculated by applying SOD values.

(III). Determination of Glutathione Peroxidase Activity:

The tissue was homogenized in 5-10 mL cold buffer (50 mM Tris-HCl, pH 7.5, 5 mM EDTA and 1 mM DTT (Dithiothreitol) per tissue. Then, it was centrifuged at $10000 \times G$ for 15 minutes, at $4^{\circ}C$. The supernatant was removed after centrifugation. The blood was centrifuged at $700 - 1000 \times G$ for 10 minutes, at $4^{\circ}C$. The serum was removed. The GPx activity was measured in liver tissue and serum samples. The GPx activity was determined via Cayman's GPx assay kit (Cayman Chemical Co., Ann Arbor, MI, USA) in Bio-Tek ELx-800. The GPx activity was measured indirectly by a coupled reaction

with glutathione reductase. The oxidized glutathione was produced upon reduction of hydroperoxide by GPx. The results were expressed as units per mg protein (U/mg) tissue, for liver tissue, and units per milliliter (U/mL), for serum. The dynamic range of the assay is only limited by the accuracy of the absorbance measurement.

(IV). Determination of Nitric Oxide Level The tissue was homogenized in PBS (pH 7.4) and centrifuged at $10000 \times G$ for 20 minutes to create the supernatant. Total NO assay was performed by spectrophotometry at 540 nm using nitrate/nitrite colorimetric assay kit (Cayman, Ann Arbor, Michigan USA) in Bio-Tek ELx-800. The assay was based on nitrate and nitrite determinations. The nitrate and nitrite are the stable end products of the reaction of NO with molecular oxygen. The total accumulation of nitrate and nitrite in serum and liver tissue was measured. The results were expressed as $\mu\text{m/g}$ protein.

(V). Determination of MPO Activity The quantitative detection of MPO was used by an enzyme-linked immunosorbent assay (ELISA) kit (MPO Instant Elisa, eBioscience, Vienna, Austria) in Bio-Tek ELx-800. The results were expressed as ng/mL protein.

(VI). Histopathology of Liver Tissue The liver tissue was also removed for histopathological investigation. The specimens were fixed in 10% formalin subsequent overnight and then were dehydrated by immersion in a series of alcohol solutions of various concentrations, cleared in xylene and paraffin embedded tissue sections. The tissue samples were then infiltrated with paraffin as blocks, sectioned (5 μm -thick slides). The prepared samples were examined under a light microscope according to the severity of the lesions modified from Yehia *et al* (2007). Each parameter was scored between 0 and 3 (0: normal, 1: mild, 2: moderate and 3: severe) and according to the point total, lesions were classified into three grades (grade 1: 1-5 points, grade 2: 6 - 10 points and grade 3: 11-15 points) (Andreoli, *et al*, 1995 and Klebanoff, 1999).

Six parameters of liver damage were evaluated:

1. Sinusoidal dilatation;
2. Distortion radial alignment around central vein;
3. Vacuolization in hepatocytes;
4. Inflammation in the portal area and around central vein;
5. Hepatocellular necrosis;
6. Eosinophils infiltration of in the periportal field or around central vein.

(VII). Statistical Analysis Data were analyzed using a commercially available statistics software package (SPSS Statistics for Windows, Version 20.0. IBM Corp., Armonk, NY, USA). All data were presented as the mean \pm SD for comparisons. Comparisons between groups were performed using the KruskalWallis analysis of variance for unpaired comparisons, followed by the Mann Whitney U test. The $P < 0.05$ was considered significant.

RESULTS AND DISCUSSION

(I). Biochemical Results

The levels of NO and MPO in serum and liver tissue were found to be significantly increased in the DI group, compared to control group ($P < 0.0001$) (Tables 1 and 2). The activity of ALT and AST were found to be significantly increased in DI group, compared to control group ($P < 0.001$) (Table 1). The levels of NO and MPO in serum were found to be significantly decreased in DMBA + silibinin group, compared with DI group ($P < 0.01$ and $P < 0.001$). When comparing DMBA + silibinin group to DMBA group the activities of AST and ALT were found decreased (Tables 1 and 2). There was no significant statistical difference between the tissue or serum GPx activities, for all groups. The serum and tissue SOD activity was found increased in DMBA + silibinin group, when compared to DI group ($P < 0.001$) (Table 1).

Groups	AST, U/L	ALT, U/L	SOD, U/mL	GPx, U/mL	NO, $\mu\text{m/g}$	MPO, ng/mL
Control group	107.63 \pm 22.37	55.13 \pm 13.04	0.1 \pm 0.02	3.48 \pm 0.98	1.43 \pm 0.73	1.51 \pm 1.02

(II). Histopathological Results

Hepatocytes of control group (Figure 1 A) and silibinin group (Figure 1 B) were observed to have a normal structure (Figure 1). It was determined histopathologically that the liver tissue intoxicated by DMBA was significantly damaged (Grade 3).

In histopathological examination, rats administered DMBA showed severe sinusoidal dilatation, moderate disrupt radial alignment of hepatocytes, severe vacuolization of hepatocyte cytoplasm, and centrilobular necrosis ($P < 0.05$) (Figure 2). In contrast, rats in DMBA + Silibinin group exhibited these changes

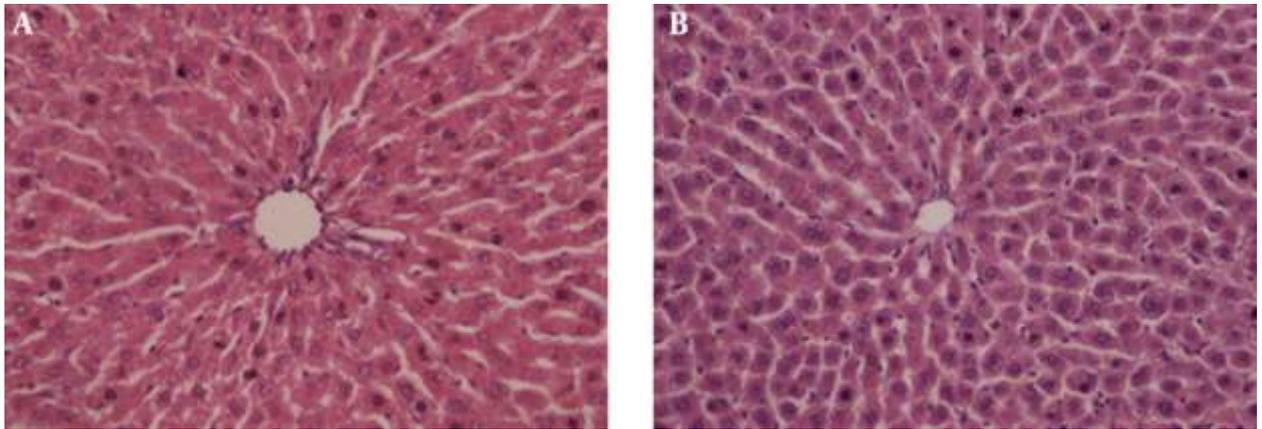

Figure 1 : Histological Structure of Liver in the Norwegian Rat, *Rattus norvegicus* (L). A: Untreated Control Group (H & E \times 40) B: Silibinin Treated Group Group (H & E \times 40). -----

significantly, especially inflammation around the central vein and portal space ($P < 0.05$) (Figure 3). The levels of ALT, AST, NO and MPO in serum were found increased in DI group, when compared with control group. We suggest that DMBA induced a significant liver damage. Silibinin reduced the levels of AST, ALT, NO, MPO in silibinin + DMBA group, compared with DI group. Silibinin, given to rats with DMBA, showed a significant protective activity against liver damage induced by DMBA. In addition, the level of SOD in serum and liver tissue increased via silibinin in silibinin+DMBA group (Table 2). In histopathological examination, DMBA caused severe sinusoidal dilatation and severe vacuolation, inflammation around the portal area and central vein and disrupted the radial alignment around the central vein in hepatocytes. Silibinin significantly reversed the DMBA-induced sinusoidal dilatation, severe vacuolization and inflammation around the central vein in hepatocytes ($P < 0.05$) (Yehia, *et al*, 2007 and Alp, *et al*, 2011). The liver is a very crucial organ for the detoxification processes and oxidative stress is thought to be a key mechanism of hepatocellular injury. The liver tissue was the major site of DMBA metabolism, by assembling a great quantity of its metabolites (Giray, *et al*, 2011). In the present study, we suggest that DMBA increased the reactive oxygen species (ROS) in liver tissue and

silibinin carries out free-radical-eliminating activity and extensive antioxidant effect. Similarly, in previous studies, it was been shown that DMBA caused increases in lipid peroxidation (Yilmaz, *et al* , 2012 and Akturk, *et al* , 2007). It was reported that DMBA exposure has been implicated in inducing oxidative stress increased nitrate and nitrite. The MPO, which is a peroxidase enzyme that synthesizes hypochlorous acid from H₂O₂ and chloride, plays an important role, as a powerful oxidant, which utilizes free radicals (Klebanoff, 1999; Mehta, *et al* , 2009; Klebanoff, 2005; Heinecke, *et al* , 1993). In this study, DMBA exposure could induce oxidative stress by the increased NO, MPO concentrations, which should induce membrane lipid peroxidation, resulting in liver injury. These results were correlated with previous reports of Messarah *et al.* who showed DMBA might generate ROS (Messarah, *et al* , 2013). It was reported that silibinin has antioxidant effects (Sozmen , *et al* , 2014). To the best our knowledge, the current study is the first to investigate the silibinin antioxidant effects on DMBA induced hepatotoxicity. Oxidative stress induced by DMBA administration is also demonstrated by a highly significant increase in the activities NO and MPO and our results are in agreement with previous reports (Messarah, *et al* , 2013 Sozmen , *et al* , 2014). The DMBA affects the mitochondrial membrane transportation in rat liver

(Nakagawa and Moore 1999). Diazinon (Lee, *et al* , 1991) and DMBA (Vitthalrao B. Khyade, *et al* , 2014) binds extensively to biological membranes, especially to the phospholipids bilayers.

Silibinin acts on the polar head group of phospholipids of the cellular membrane. It was reported that silibinin act as an excellent protective agent against lipid peroxidation on cellular membrane (Erlejman, *et al* , 2004). Previous studies have reported the protective role of silibinin via scavenging free radicals and antioxidant properties (Gazak, *et al* , 2007). Silibinin is membranotropic in nature and it has been found to bind firmly to the hepatocellular membrane. Silibinin has a role in metabolic and cell-regulating actions via antioxidative mechanism, which is regarded as a major hepatoprotective effect. In addition, ALT and AST enzymes activities represent a marker of hepatic function when determining hepatotoxicity. The DMBA exposure resulted in the increase of the activities of serum AST and ALT. The phenomenon may occur due to disturbing the transport function of the hepatocytes. In a previous study, silibinin repair function in hepatotoxicity was reported thorough the reduction in the serum levels of ALT and AST enzymes (Cacciapuoti, *et al* , 2013). Probably, increases of serum ALT and AST enzymes activities are one of the important markers for the diagnosis of liver damage. In addition, by increasing MPO, NO levels, DMBA plays role in pathogenesis of hepatic toxicity via oxidative stress mechanism. The MPO, which is the most abundant protein in neutrophils and catalyzes the conversion of hydrogen peroxide and chloride ions into hypochlorous acid, plays a role in down-regulating the inflammatory response (Klebanoff,1999). However, in non-infectious diseases, MPO that was found increased was associated with strong oxidative activity. The activity of MPO in the oxidation of DMBA was reported previously (Lazarević-Pašti, 2011). Silibinin counteracted the inflammatory process by decreasing the MPO pathway and also by preventing free radical production. Liver injury, marked as centrilobular necrosis and neutrophilic infiltration around centrilobular area, could be seen in H & E stained rat liver cells. In this study, the activity of MPO and histopathological results are correlated about hepatotoxicity. Silibinin has been intensively studied in vitro, in vivo and also, in clinical trials. Van Wenum *et al* (2013) reported that silibinin used in the treatment of cirrhosis, hepatitis and alcohol-induced liver disease, is usually connected with antioxidant action (van Wenum, *et al* , 2013). Silibinin is extensively applied due to its safety and lack of adverse effects. We found an increased activity of plasma antioxidant enzymes, namely SOD in DMBA + silibinin group. The SOD is assumed to be the most effective antioxidant (Sirmali, *et al* , 2013). Therefore, it is regarded as the first line of defense against the

detrimental effects of molecular oxygen radicals in cells. Superoxide is a crucial source of hydroperoxides and free radicals. The activity of SOD inhibits lipid peroxidation by catalyzing the conversion of superoxides into hydrogen peroxide and oxygen (Beyer, *et al* , 1991; Vitthalrao B. Khyade and Aziz Sancer, 2016). The SOD protects the cells from superoxide toxicity via removing superoxide free radicals. Silibinin also restored SOD activity. The increased hepatic SOD activity we observed in the group treated with silibinin. Accordingly, the co-administration of silibinin, after DMBA exposure, increased SOD levels and ameliorated the oxidative system. The co-administration of silibinin reduced the detrimental effects of DMBA by possibly scavenging or neutralizing ROS. These results showed that silibinin might have a beneficial role in lowering DMBA toxicity. Furthermore, a protective effect of silibinin has also been reported against N-nitrosodimethylamine induced oxidative stress. Silibinin caused increases of SOD in liver tissue against N-nitrosodimethylamine (Ezhilarasan, *et al* , 2012; Vitthalrao B. Khyade , 2016).

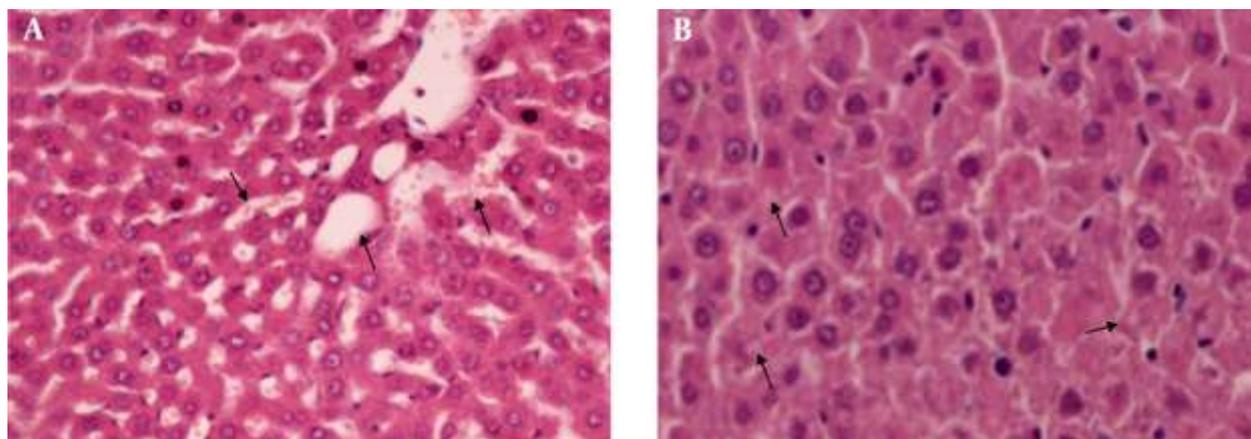

Figure 3: Histological Structure of Liver in the Norwegian Rat, *Rattus norvegicus* (L) (DMBA+Silibinin-Group)

A: Mild dilatation in sinusoid (arrows) (H & E x 100).
B: Minimal vacuolation (arrows) (H & E x 200).

Lipid peroxidation starts as a consequence of ROS-induced isolation of hydrogen from polyunsaturated fatty acids (PUFAs) from the cellular membrane, which results in the formation of relatively stable compounds, like NO. Increasing the level of NO has a crucial role in the modulation of oxidative stress and tissue damage (Tutanc, *et al* , 2012). It was reported that oxidative stress results in increasing the activity of NO synthase, as a consequence of the elevation of NO release (Peresleni, *et al* , 1996). The DMBA induced the secretion of excess NO reaction with the superoxide anion to generate the peroxynitrite radical involved in the toxification process. Silibinin treatment significantly reduced lipid peroxidation, as an antioxidant. Therefore, silibinin treatment repaired the excess NO reaction. Treatment with silibinin effectively decreased the levels of NO. It has been reported that silibinin scavenges nitrogen species. Similarly, Prabu *et al* (2012) found that the level of NO decreased as a result of silibinin treatment against arsenic induced toxicity (Prabu, *et al* , 2012; Vitthalrao B. Khyade and Sadhana D. Deshpande , 2015). The GPx is a crucial selenocysteine-containing enzyme, which catalyzes the reduction of hydroperoxides, including hydrogen peroxide, by reduced glutathione and functions to protect the cell from oxidative damage (Arthur, 2000 ; Vitthalrao B. Khyade and Ujwala D. Lonkar, 2013). It was reported that DI induced oxidative toxicity through oxidation of GPx (Shadnia *et al* , 2011).

In another study, the GPx activity values were found to be non-significantly different between the DMBA group and DMBA + N-acetyl cysteine group. Similarly, in our study, GPx activity was not found significantly different between DMBA group and DIMBA + silibinin group.

Conclusively enough, the attempt demonstrate that silibinin exerts hepatoprotective, antioxidant, free radical scavenging effects against DMBA induced hepatotoxicity. It may be suggested that silibinin is convenient as a therapeutic agent for the amelioration of DMBA induced hepatotoxicity. However, further studies are required in order to understand and quantify the beneficial effects of silibinin in DMBA induced hepatotoxicity and it's possible clinical use.

ACKNOWLEDGEMENTS:

The author thank the head and staff members of the department of Zoology, Savitribai Phule University, Pune for support and guidance. Experimental Research Center, Isparta, Turkey and Mugla Sitki Kocman University Scientific Research Projects deserve appreciations and exert a grand salutary influence for financial and technical supports. Author would like to express his gratitude towards the dignitaries of International Journal of Innovative Research for kind co-operation and encouragement, which served a lot to orchestrate the progression of publication of present research work.
